ABSTRACT

Aims: this study sought to assess the reproductive performance of sows inseminated with sperm treated with homeopathic medicines. Materials and methods: the semen of 2 sexually mature boars age 18 months Pietrain and Duroc cross-bred with similar genetic and reproductive performance were chosen, as well as 125 sows. Sixteen samples of semen were collected and standardized through semen evaluation. Three homeopathic preparations and a placebo (control) were tested on the sperm (n=31/32 per group): Avena sativa 6cH, Pulsatilla nigricans 6cH and Avena sativa 6cH + Pulsatilla nigricans 6cH. Sows were inseminated 3 times with the same estrous diagnostic procedures. Results: there was significant difference (p<0.05) between Avena sativa 6cH and the other 3 groups regarding the return to estrus and parturition rate. There was no significant difference among the groups regarding the number of newborn piglets. Conclusion: these data suggest that homeopathic preparation Avena sativa may be used directly on sperm cells to improve the parturition rate in technified swine farms. Key Words: swine, reproductive performance, semen, homeopathy, blind-controlled study.

1. Introduction

Artificial insemination is used to increase reproductive efficiency and productivity in the production of swine [1]. Although this technology is already established, there is a constant need to improve the reproductive zootechnical results of herds when using this procedure [2]. The demand for new researches and alternative products to improve the quality of swine semen and to decrease costs [3] is growing in middle- and large-sized swine farms worldwide [4].

https://doi.org/10.51910/ijhdr.v9i30.375
Different protocols have been applied to semen to improve its quality and consequently to improve the parturition rate and the number of newborns [5, 6, 7]. Although there are few studies on the effect of homeopathic medicine directly applied to the semen in order to stimulate the activity of the sperm cells and the fecundity rate in swine herds [8], this seems to be a promising way to improve reproductive results. Among the homeopathic preparations that can be used for reproduction in human beings and domestic animals *Avena sativa* and *Pulsatilla nigricans* are mentioned in the literature. *Avena sativa*, prepared from oat, has been described as influencing different metabolic processes, mainly the ones related to reproduction, through an action on the male reproductive system and a positive effect on the sperm cells [9]. *Pulsatilla nigricans* or *Anemona pratensis* belongs to the Ranunculaceae family and grows in windy slopes of Europe. It provokes benefic effects in the reproductive system of domestic animals, on both male and female organs, improving fertility and consequently also reproduction [10]. The positive effect of *Avena sativa* and/or *Pulsatilla nigricans* on the fecundity of human beings and domestic animals as already been reported [11, 12].

The aim of this study was to test the effect of both homeopathic remedies separated and in combination on sperm cells of boars in order to evaluate the reproductive performance of sows inseminated with that semen.

2. Materials and Methods

2.1 Experimental method

The experiment was developed during 7 months between April 20th and November 20th, 2008, at the artificial insemination facility of a commercial swine farm with 200 sows at Ibiúna, São Paulo, Brazil. The semen of 2 mature boars aged 18 months was used. Boars were Pietrain and Duroc cross-bred, with similar genetic and reproductive performance, progeny BP 450®, originated from the same sows and boars production farm (table 1). Animals were housed in individual stalls with heat control and fed with 16% crude protein of ground corn, soy dust, corn germ, vitamin and mineral supplementation without antibiotics.

In order to standardize the treated and control groups of inseminated sows, 125 Landrace and Large White cross-bred with similar genetic breeds, progeny BP 400® (table 1), from the same sows and boars production farm and with reproductive cycle between the first and fifth parturition were distributed among experimental groups.

Sows were housed at the same facility with identical nutritional handling and sanitary conditions.

2.2 Semen collection, sperm evaluation and dilution

Sixteen semen collections were made for both boars always in the same day and time, once a week. Semen was standardized through sperm evaluation at the insemination facility as soon as it was collected according to the minimum cut point parameters: 90% sperm motility, 3 billion sperm cells per 100 mL bottle of diluted semen and sperm vigor equal to score four [13,14]. Sperm concentration was determined with a numeric scale sperm densimeter. Sperm vigor was numerically quantified using optic microscope, with score zero for dead sperm cells, 1 for low vigor, 2 for medium vigor, 3 for satisfactory and 4 for high [13-14]. Sperm motility was
also quantified using an optic microscope. In this case, the minimum percentage zero applied to dead sperm cells and the maximum 90 to high motility sperm cells. The semen was diluted in MIII® brand, from Minitub Company. Diluted semen was stored at 18°C in 100mL plastic bottles. Semen motility and vigor of both treated and control groups were evaluated at the harvesting time just after dilution (time zero).

2.3 Homeopathic preparations

Three homeopathic preparations and 1 placebo (inert vehicle), *Avena sativa* 6cH, *Pulsatilla nigricans* 6cH, *Pulsatilla nigricans* 6cH plus *Avena sativa* 6cH, were used to compose 3 treated groups and 1 control. Both the homeopathic preparations and the inert vehicle were coded to carry out a blind controlled study; the code was only known by the pharmacy that prepared the tested solutions. All 3 homeopathic preparations and the placebo were prepared as 30mg saccharine embedded globules, according to the Brazilian Homeopathic Pharmacopeia [15, 16, 17, 18]. The control group received globules not impregnated with active substances. Two globules were diluted per 100mL of diluted semen at once. The corresponding codes were recorded on the tube at this moment.

2.4 Experimental groups and insemination of sows

Four groups were constituted: control (n=31), *Avena sativa* (n=31), *Pulsatilla nigricans* (n=32) and *Avena sativa* plus *Pulsatilla nigricans* (n=31). Using Suinsoft® software [19], 125 sows with similar reproductive performance were selected and randomly distributed among the treated and control groups. The sows from all the 4 groups were inseminated three times with the same estrous diagnostic procedure.

The first insemination was made when the male tolerance reflex was detected and the following 2 inseminations were carried out at 2 hours intervals. [14]. Suinsoft® [19] software was used to calculate the results in the treated and control groups regarding to the number of female parturitions and return to estrous. Microsoft Excel® software was used for plotting the total number of newborn piglets and the fertility rate.

2.5 Statistics

The comparison of parturition rate and return to estrous rate between groups was made through Chi-Square test. To compare the total median number of newborn piglets Kruskal-Wallis test was used [20]. Significance level was 5%, and all analyses were made with software Minitab® 14.0.

Suinsoft® software [19] was used to calculate the results in the control and treated groups regarding the parturition number and the number of return to estrous; for the total number of newborns and the fertility rate software Microsoft Excel® was used.

3. Results

Table 2 shows the results of the parturition numbers and their respective percentages, the number of return to estrous and newborn piglets, for the control and treated groups.

Regarding the parturition rate and the proportion of return to estrous there was significant difference (p<0.05) between *Avena sativa* and the other groups: *Pulsatilla nigricans*; *Avena sativa* + *Pulsatilla nigricans* and control. There was no significant difference among the groups regarding the total median number of newborn piglets (p>0.05). There was no statistical significance between any of the groups regarding the parturition percentage.

4. Discussion

The semen treated with *Avena sativa* exhibited the best and significant results regarding to parturition, with the lowest number of sows that returned to estrous after insemination and, consequently, higher fertility rate when compared to *Pulsatilla nigricans*, *Avena sativa* + *Pulsatilla nigricans* and control groups. *Pulsatilla nigricans* either alone or associated to *Avena sativa* presented negative effect on the sperm cells resulting in lower parturition rates for the two groups in which it was, although the literature describes this plant as beneficial for the reproductive system of domestic animals [10]. Even though the mean of newborn piglets was higher for the group treated with *Avena sativa* by comparison to the control and the groups treated with *Pulsatilla nigricans* or *Avena sativa* + *Pulsatilla nigricans* no statistical significance was detected. The results obtained for *Avena sativa* in diluted semen are, thus, encouraging for the purpose of increasing the fecundity rate of swine herd.

Previous studies have shown the beneficial effect of the use of some homeopathic preparations applied directly on sperm cells: Soto et al.[8] obtained similar results using *Avena sativa* in swine semen. In this case there was 83% parturition rate, as well as improvement of vigor and sperm motility, even after 24 hours of semen harvesting. Aziz and Enbergs [21] demonstrated that homeopathic treatment of bovine cooled frozen semen with different dilutions of monoensin (5 up to 14 times) resulted in a significant increase of the mitochondrial activity of sperm cells measured by cytometry, even though a negative effect was observed on the semen viability.

Radkumar et al [22], conducted a study to assess the effectiveness of a homeopathic complex (*Calcarea phosphorica* 30cH, *Aletris farinosa* 30cH, *Pulsatilla* 30cH, *Aurum muriaticum natronatum* 30cH, *Sepia* 30cH and *Phosphorus* 30cH) in the treatment of rue anoestrus in cows, being scored as 100% effective in inducing with no return to estrus; also, a steady increase in the concentration of estradiol was observed in the treated animals, maybe due to the presence of *Pulsatilla* in the complex [9, 10, 11].

New researches must be developed with other homeopathic preparations or associations that have a putative ability to improve the parturition rate and the number of newborn piglets at the same time. In this study, *Avena sativa* showed a specific ability to reduce the number of return to estrous and consequently to improve the parturition rate in experimental conditions; the economic impact of this improvement in a technified herd production seems promising. Supposing the systematic implantation of this technology in a 1000-sow herd, there would be a reduction of 360 inseminations per year, or 2.4 parturitions per year /sow, (2400 total, with this technique) versus 2.04 (2040 total, without this technique)[8, 23].

In conclusion, *Avena sativa* as a homeopathic preparation can be indicated directly in sperm cells in order to improve the parturition rate in technified swine farms.

Rendimiento reproductivo de porcinos inseminados con esperma tratado con medicamento homeopático

RESUMEN

Objetivos: este estudio buscó evaluar el rendimiento reproductivo de suínos inseminados con esperma tratado con medicamentos homeopáticos. Materiales y métodos: el esperma de dos suínos sexualmente maduros de 18 meses de edad híbridos Pietrain y Duroc, con rendimiento genético y reprodutivo similares fue seleccionado, así como 125 fêmeas. De sesenta y dos muestras de esperma fueron colectadas y estandarizadas a través de análisis del esperma. Trés preparaciones homeopáticas y un control (placebo) fueron testados en el esperma (n=31/32 por grupo): Avena sativa 6cH, Pulsatilla nigricans 6cH y Avena sativa 6cH + Pulsatilla nigricans 6cH. Las fêmeas fueron inseminadas 3 veces con los mismos procedimientos de diagnóstico del estro. Resultados: hubo diferencia significativa (p<0,05) entre Avena sativa 6cH y los otros 3 grupos en el retorno al estro y taxas de partos. No hubo diferencia significativa entre los grupos en el número de recién nacidos. Conclusión: los datos sugieren que la preparación homeopática Avena sativa puede ser utilizada directamente en las células espermáticas para mejorar la tasa de partos en la ganadería de porcinos.
